Cardiovascular risk in atopic eczema is only associated with active disease in adulthood

Adult atopic dermatitis is associated with lymphopenia in two large cohorts

Adverse reproductive outcomes among women with hidradenitis suppurativa

Entropion repair outcomes in ocular cicatricial pemphigoid versus other cicatricular etiologies: A retrospective study

Large scale epidemiological analysis of common inflammatory skin diseases to identify shared and unique comorbidities and demographic factors

Laboratory abnormalities in atopic dermatitis (AD) are poorly understood and lymphopenia could occur due to skin homing of lymphocytes. We aimed to determine the extent to which AD is associated with lymphopenia in two large population-based cohorts from the UK and US: CRPD and the 2005-2006 UK eMERGE. Using logistic regression models adjusted for age, sex, ethnicity, socioeconomic status, we found an increased risk of lymphopenia in those with AD in both cohorts: OR 1.15, 95%CI 1.09-1.21 in CRPD (168,256 people with AD), and OR 2.77, 95%CI 1.04-7.39 among UK eMERGE participants attending a Mobile examination center with self-reported AD in the previous year. In CRPD, we found that the magnitude of asso-

Using logistic regression models adjusted for age, sex, ethnicity, socioeconomic status, we found an increased risk of lymphopenia in those with AD in both cohorts: OR 1.15, 95%CI 1.09-1.21 in CRPD (168,256 people with AD), and OR 2.77, 95%CI 1.04-7.39 among UK eMERGE participants attending a Mobile examination center with self-reported AD in the previous year. In CRPD, we found that the magnitude of association increased with increasing AD severity (OR 1.89, 95%CI: 1.54-2.12). The association was attenuated after adjusting for immunosuppressive drug use (including systemic corticosteroids) in both cohorts, but persisted in the UK data (OR severe AD without adjustment 2.85, 95%CI: 1.42-5.72; OR severe AD after adjustment 1.45, 95%CI: 1.04-2.02). In both cohorts there was no association between AD and total white blood cell count which was used as a negative control. In conclusion, people with AD may be at risk of lymphopenia, which may not be fully explained by immunosuppressive drug use. These findings are important because lymphopenia may be a marker for immunosenescence and/or increased risk of infection and has been associated with an increased risk of mortality.
